

Oasis Infobyte – Cybersecurity Internship

Task 6 – Patch Management

This folder contains my completed Task 6 work for the Oasis Infobyte Cybersecurity Internship. The task focuses on why security patches are important and how organizations can manage updates in a controlled and repeatable way.

Objective

The objective is to understand the basic patch-management lifecycle: identifying systems, finding applicable updates, prioritizing them by risk, testing patches, deploying them, and verifying that the update was successful.

Process Covered

- Maintain an inventory of operating systems, applications and devices.
- Monitor vendors and trusted sources for available security updates.
- Prioritize patches based on severity, exposure and business impact.
- Test important patches before wider deployment when practical.
- Deploy patches using a controlled schedule or approved change process.
- Verify installation and monitor systems after deployment.
- Document exceptions and ensure postponed critical patches are reviewed.

Why Patch Management Matters

Unpatched software can contain known vulnerabilities that attackers may exploit. A consistent patching process reduces exposure and helps organizations keep systems at a safer security baseline.

What I Learned

This task helped me understand that patching is more than simply clicking an update button. Good patch management involves inventory, risk assessment, testing, deployment, verification and documentation.

Repository Contents

The folder contains the Task 6 report and this README. Together they document the topic and the learning process followed for the internship task.

Purpose

This work was completed for educational and internship purposes as part of the Oasis Infobyte Cybersecurity Internship.
